We report the crystallographic and magnetic properties of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  by means of X-ray diffractometer (XRD), a superconducting quantum interference device (SQUID) magnetometer, and a Mössbauer spectroscopy. In particular,  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  was studied by Mössbauer analysis for evidence of spin reorientation. The chalcogenide material  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  was fabricated by a direct reaction method. XRD analysis confirmed that  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  has a 2-dimension (2-D) triangular lattice structure, with space group  $P\bar{3}m1$ . The Mössbauer spectra of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  at spectra at various temperatures from 4.2 to 300 K showed that the spectrum at 4.2 K has a severely distorted 8-line shape, as spin liquid. Electric quadrupole splitting,  $E_Q$  has anomalous two-points of temperature dependence of  $E_Q$  curve as freezing temperature,  $T_f = 11$  K, and Néel temperature,  $T_N = 26$  K. This suggests that there appears to be a slowly-fluctuating “spin gel” state between  $T_f$  and  $T_N$ , caused by non-paramagnetic spin state below  $T_N$ . This comes from charge re-distribution due to spin-orientation above  $T_f$ , and  $T_N$ , due to the changing  $E_Q$  at various temperatures. Isomer shift value ( $0.7 \text{ mm/s} \leq \delta \leq 0.9 \text{ mm/s}$ ) shows that the charge states are ferrous ( $\text{Fe}^{2+}$ ), for all temperature range. The Debye temperature for the octahedral site was found to be  $\Theta_D = 260$  K.

**Keywords :** mössbauer spectroscopy, spin reorientation, electric quadrupole splitting

### 1. Introduction

The chalcogenide materials have attracted interest for their various physical properties of colossal magnetoresistance [1], gigantic Kerr effect [2], orbital glass state [3], spin dimerization [4], and spin-frustration [5, 6]. The materials with triangular lattice for  $\text{AGa}_2\text{S}_4$  ( $A = \text{Mn, Ni, Fe, Co, Zn}$ ),  $\text{Gd}_3\text{Ga}_5\text{O}_{12}$ ,  $\text{Fe}_2\text{OBO}_3$  and so on, have reported characteristic geometrical frustration phenomena. Their materials have non-conventional magnetic order, arising from the incommensurate spin structure, spin fluctuation, spin-flop, and spin liquid without spin solid below Néel temperature [7-9]. In particular, research interest has focused on triangular lattice antiferromagnet  $\text{NiGa}_2\text{S}_4$ , which has a low spin state of  $S = 1$ , despite geometrical frustration, spin-fluctuation, and the atomic short-range order in the ground state up to 0.35 K [5]. Meanwhile, it was reported that  $\text{FeGa}_2\text{S}_4$  with geometrical frustration phenomena, like the crystal structure of  $\text{NiGa}_2\text{S}_4$  has a high spin state of spin = 2 at low temperature [10]. Recent-

ly,  $\text{NiGa}_2\text{S}_4$  and  $\text{FeGa}_2\text{S}_4$  have magnetic transition with  $T^* \cong 9$  and 30 K, with presence of spatial inhomogeneity from muon spin rotation and relaxation ( $\mu\text{SR}$ ) experiments [11]. This coincides almost with Néel temperature  $T_N$  of 11, and 33 K of  $\text{NiGa}_2\text{S}_4$  and  $\text{FeGa}_2\text{S}_4$ , respectively, by Mössbauer spectroscopy [12-14]. In this paper, we describe crystallographic and magnetic properties of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$ , when Fe is doped at 70 % in  $\text{NiGa}_2\text{S}_4$  by using an X-ray diffractometer (XRD), a superconducting quantum interference device (SQUID) magnetometer, and a Mössbauer spectroscopy. Especially, we report evidence of spin reorientation of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  by Mössbauer analysis.

### 2. Experimental Details

The polycrystalline sample of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  was prepared by a standard solid-state reaction method in evacuated  $10^{-7}$  torr quartz ampoules. In order to obtain homogeneous materials, it was necessary to grind the mixed powders of Fe (99.99%), Ni (99.99%), Ga (99.999%), and S (99.99%), and press the powder into pellet, before the annealing process in evacuated quartz ampoules. A single phase of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  was obtained, by annealing at 1000°C with nitrogen gas in evacuated quartz

ampoules for ten days. The crystal structure of sample of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  was analyzed, by using Philips X'Pert diffractometer with  $\text{Cu K}\alpha$  radiation source. The magnetic properties were characterized by superconducting quantum interference device (SQUID) magnetometer. The Mössbauer spectra were recorded by conventional spectrometer of the electromechanical type, with a  $^{57}\text{Co}$  source in a rhodium matrix. The obtained Mössbauer spectra were analyzed by a least-squares fitting program.

### 3. Results and Discussion

The XRD pattern of single-crystal  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  at room temperature was analyzed by Rietveld's refinement of the FullProf code, as shown in Fig. 1. The crystalline structure of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  was a 2-dimension triangular lattice of space group  $P\bar{3}m1$ , and the lattice parameters were  $a_0 = 3.657 \text{ \AA}$ , and  $c_0 = 12.058 \text{ \AA}$ . The Bragg factor  $R_B$  and the structure factor  $R_F$  were less than 4%. The interlayer path  $\theta_{\text{Fe-S-Fe}}$  ( $^\circ$ ) for  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  is  $98.16^\circ$ , and the lattice parameters of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  are shown in Table 1. Also, we confirmed that the structure of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  consists of a central  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{S}_2$  layer of edge-sharing  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{S}_6$  octahedral site, and top of the bottom sheets of  $\text{GaS}_4$  tetrahedral site. The layered structure is formed by four anion sulfur layers, which are stacked in the direction of the c-axis, as in distorted hexagonal structure.

**Fig. 1.** (Color online) Refined x-ray diffraction pattern of the  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  at room temperature. The Bragg factors  $R_B$  and the structure factors  $R_F$  were under 4%.

**Fig. 2.** (Color online) Temperature dependence of molar susceptibility  $\chi$  of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  in zero-field-cooled (open symbols) and field-cooled (solid symbols) magnetization, at magnetic fields under 100 Oe. Inset shows the inverse molar susceptibility  $1/\chi$  in field-cooled (FC) magnetization, at magnetic fields under 5 T.

Fig. 2 presents the temperature dependences of zero-field-cooled (ZFC) and field-cooled (FC) molar susceptibility, in an external magnetic field of  $H = 100 \text{ Oe}$ , measured by SQUID magnetometer. The magnetic irreversibility appears below freezing temperature  $T_f = 11.0 \text{ K}$ , as shown with two different temperature dependencies. This spin-freezing transition temperature,  $T_f$  coincides with the temperature of changing from 8-line into 2-line width of Mössbauer spectrum. From the inset of Fig. 2, showing the temperature dependence of inverse susceptibility  $\chi^{-1}$  in field-cooled (FC) magnetization under 5 T, we determined Curie–Weiss temperature for  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  to be  $\theta_W = -90.54 \text{ K}$ . Also, antiferromagnetic behavior is clearly indicated, and the frustration factor ( $|\theta_W|/T_N$ ) is 8.23.

The Mössbauer spectra for  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  were obtained at various temperatures ranging from 4.2 to 300 K as shown in Fig. 3. The Mössbauer spectra show severely distorted 8-line shape from 4.2 K to  $T_f = 11 \text{ K}$  due to the geometrical frustration effect, as spin-fluctuation, incommensurate spin structure, atomic short-range ordering, and liquid spin state. We analyzed the Mössbauer spectra by using the full Hamiltonian for the  $^{57}\text{Fe}$  nucleus and considering both the magnetic dipole and the electric

**Table 1.** XRD refinement parameters of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  at room temperature, for a  $P\bar{3}m1$ , 2-dimensional triangular lattice structure.

sample	$a_0$ (Å)	$c_0$ (Å)	$V$ (Å <sup>3</sup> )	$d_{\text{Fe-Fe}}$ (Å)	$d_{\text{Fe-S}}$ (Å)	$\theta_{\text{Fe-S-Fe}}$ ( $^\circ$ )
$\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$	3.657	12.058	3.657	3.657	2.420	98.16

quadrupole interactions. From the value of the isomer shift value ( $0.7 \text{ mm/s} \leq \delta \leq 0.9 \text{ mm/s}$ ) at all temperature range, we concluded that the Fe ion is ferrous ( $\text{Fe}^{2+}$ ). We determined that  $T_f$  is 11 K, due to the appearance of 2-line from 8-line width of Mössbauer spectrum, in accord with  $T_f$  from SQUID magnetometer. We decided on the small gap energy,  $\Delta_1 = 0.208 \text{ meV}$  for the doublet levels of  ${}^5T_{2g}$  between  ${}^5T_{2g}$  and  ${}^5E_g$  states on the ground state of  ${}^5D$  for  $\text{Fe}^{2+}$  ion based on crystal field energy theory from electric quadrupole splitting,  $E_Q = 1.82 \text{ mm/s}$  at 4.2 K [15]. Fig. 4 shows the ratio of the intensities,  $R_q = A_1/A_2$ , between the Mössbauer absorption areas in the two electric quadrupole splitting in the temperature range from 12 to 300 K.

Then, we determined that Néel temperature,  $T_N$  is 26 K, since the meeting temperature of the slopes is 26 K, when the slopes of  $R_q$  at lower and higher temperature are connected. The decreases of  $R_q$  from 1.34 to 1.07 with increasing temperature comes from the Goldanskii-Karyagin effect, which is caused by the asymmetric environment, extensive quadrupole splitting and anisotropic thermal vibrations [16].

As shown in Fig. 5, electric quadrupole splitting,  $E_Q$  decreases at  $T_f$  with frozen disordered-spins around  $T_f$ , as in spin-liquid material, and increases of  $E_Q$  above  $T_f$  shows charge re-distribution due to spin-orientation. However, there is no complete spin-orientation at  $T_f$  due to additional increases of  $E_Q$  at  $T_N$  with evidence of spin-

**Fig. 4.** (Color online) Ratio of the intensities of two lines,  $R_q = A_1/A_2$ , for  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  in the temperature range from 12 to 300 K for the Mössbauer spectra.

**Fig. 5.** (Color online) Temperature dependence of the electric quadrupole splitting for  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$  from 12 to 300 K.

reorientation. Finally, this suggests that a viscous “spin gel” regime with nearly-frozen spin state, and slowly fluctuating, exists between  $T_f$  and  $T_N$ , caused by the absolute paramagnetic disordered-spin at  $T_N$  [11]. The Debye temperature for octahedral site can be calculated from the temperature dependence of the resonant absorption area for each sub-spectrum at low temperatures, as shown in Fig. 6. The calculated Debye temperature octahedral site was  $\Theta_D = 260$  K.

#### 4. Conclusions

We have investigated the crystallographic and magnetic properties of  $\text{Ni}_{0.3}\text{Fe}_{0.7}\text{Ga}_2\text{S}_4$ . The crystal structure of the sample is found to be 2 D-triangular lattice with space group  $P-3m1$  from a Rietveld refinement of the XRD data. From SQUID measurements, the sample showed an antiferromagnetic behavior with  $\theta_w = -90.54$  K, and spin-freezing transition at a freezing temperature is  $T_f = 11$  K.  $T_N$  is determined to be 26 K from the ratio of the intensities ( $R_q = A_1/A_2$ ). We found by Mössbauer analysis that spin reorientation appeared at  $T_b$  and  $T_N$  due to the changing of  $E_Q$  at various temperatures.
